

THERMAL RECOVERY

This is accomplished either by hot fluid injection (hot water or steam) or *in situ* combustion (burning a part of the crude oil in place). Variations of these methods improve production of crudes by heating them, thereby improving their mobility and ease of recovery by fluid injection.

Steamflood Reservoir Management K. C. Hong,1994 **List of BETC Publications** Bartlesville Energy Technology Center,1977 **Thermal Processes for Heavy Oil Recovery** National Institute for Petroleum and Energy Research (Bartlesville, Okla.),A. K. Sarkar,P. S. Sarathi,1993 *Enhanced Oil Recovery* Marcel Latil,1980 **Enhanced Oil Recovery** M. M. Schumacher,1978 **Thermal Processes for Heavy Oil Recovery** ,1993 This status report summarizes the project BE11B Thermal Processes for Heavy Oil Recovery research activities conducted in FY93 and completes milestone 7 of this project A major portion of project research during FY93 was concentrated on modeling and reservoir studies to determine the applicability of steam injection oil recovery techniques in Texas Gulf Coast heavy oil reservoirs In addition an in depth evaluation of a steamflood predictive model developed by Mobil Exploration and Production Co Mobil E P was performed Details of these two studies are presented A topical report NIPER 675 assessing the NIPER Thermal EOR Research Program over the past 10 years was also written during this fiscal year and delivered to DOE Results of the Gulf Coast heavy oil reservoir simulation studies indicated that though these reservoirs can be successfully steamflooded and could recover more than 50% of oil in place steamflooding may not be economical at current heavy oil prices Assessment of Mobil E P s steamflood predictive model capabilities indicate that the model in its present form gives reasonably good predictions of California steam projects but fails to predict adequately the performance of non California steam projects

Enhanced Oil Recovery Field Case Studies James J. Sheng,2013-04-10 This chapter first reviews thermal properties of rock and fluids and related energy concepts The fundamentals of heat transfer and heat loss theories to estimate the heated area and oil recovery performance are briefly presented The mechanisms and screening criteria of steam flooding are discussed After the general practice in steam flooding projects is discussed field cases are presented which include Kern River in California Duri steam flood in Indonesia West Coalinga Field in California Karamay Field and the Qi 40 block in Laohe China **Enhanced Oil Recovery Using Flash-driven Steamflooding** ,1990 The present invention is directed to a novel steamflooding process which utilizes three specific stages of steam injection for enhanced oil recovery The three stages are as follows As steam is being injected into an oil bearing reservoir through an injection well the production rate of a production well located at a distance from the injection well is gradually restricted to a point that the pressure in the reservoir increases at a predetermined rate to a predetermined maximum value After the maximum pressure has been reached the production rate is increased to a value such that the predetermined maximum pressure value is maintained Production at maximum pressure is continued for a length of time that will be unique for each individual reservoir In some cases this step of the steamflooding process of the invention may be omitted entirely In the third stage of the steamflooding process of the invention production rates at the producing well are increased gradually to allow the pressure to decrease down from the maximum pressure value to the original pressure value at the producing well The rate of pressure reduction

will be unique for each reservoir After completing stage three the three stages can be repeated or the steamflood may be terminated as considered desirable

Transformation of Resources to Reserves, 2007 This final report and technical progress report describes work performed from October 1 2004 through September 30 2007 for the project Transformation of Resources to Reserves Next Generation Heavy Oil Recovery Techniques DE FC26 04NT15526 Critical year 3 activities of this project were not undertaken because of reduced funding to the DOE Oil Program despite timely submission of a continuation package and progress on year 1 and 2 subtasks A small amount of carried over funds were used during June August 2007 to complete some work in the area of foamed gas mobility control Completion of Year 3 activities and tasks would have led to a more thorough completion of the project and attainment of project goals This progress report serves as a summary of activities and accomplishments for years 1 and 2 Experiments theory development and numerical modeling were employed to elucidate heavy oil production mechanisms that provide the technical foundations for producing efficiently the abundant discovered heavy oil resources of the U S that are not accessible with current technology and recovery techniques Work fell into two task areas cold production of heavy oils and thermal recovery Despite the emerging critical importance of the waterflooding of viscous oil in cold environments work in this area was never sanctioned under this project It is envisioned that heavy oil production is impacted by development of an understanding of the reservoir and reservoir fluid conditions leading to so called foamy oil behavior i e heavy oil solution gas drive This understanding should allow primary cold production of heavy and viscous oils to be optimized Accordingly we evaluated the oil phase chemistry of crude oil samples from Venezuela that give effective production by the heavy oil solution gas drive mechanism Laboratory scale experiments show that recovery correlates with asphaltene contents as well as the so called acid number AN and base number BN of the crude oil A significant number of laboratory scale tests were made to evaluate the solution gas drive potential of West Sak AK viscous oil The West Sak sample has a low acid number low asphaltene content and does not appear foamy under laboratory conditions Tests show primary recovery of about 22% of the original oil in place under a variety of conditions The acid number of other Alaskan North Slope samples tests is greater indicating a greater potential for recovery by heavy oil solution gas drive Effective cold production leads to reservoir pressure depletion that eases the implementation of thermal recovery processes When viewed from a reservoir perspective thermal recovery is the enhanced recovery method of choice for viscous and heavy oils because of the significant viscosity reduction that accompanies the heating of oil One significant issue accompanying thermal recovery in cold environments is wellbore heat losses Initial work on thermal recovery found that a technology base for delivering steam other hot fluids and electrical heat through cold subsurface environments such as permafrost was in place No commercially available technologies are available however Nevertheless the enabling technology of superinsulated wells appears to be realized Thermal subtasks focused on a suite of enhanced recovery options tailored to various reservoir conditions Generally electrothermal conventional steam based and thermal

gravity drainage enhanced oil recovery techniques appear to be applicable to prime Ugnu reservoir conditions to the extent that reservoir architecture and fluid conditions are modeled faithfully here The extent of reservoir layering vertical communication and subsurface steam distribution are important factors affecting recovery Distribution of steam throughout reservoir volume is a significant issue facing thermal recovery Various activities addressed aspects of steam emplacement Notably hydraulic fracturing of horizontal steam injection wells and implementation of steam trap control that limits steam entry into horizontal production wells overcomes many of the problems associated with implementation of thermal gravity drainage processes in heterogeneous sands In a steam assisted gravity drainage SAGD well pattern hydraulically fractured injectors were able to achieve significantly improved reservoir heating and improvements to oil steam ratio On the opposite side of the steam injection spectrum steam often channels through high permeability zones Foamed steam stabilized by aqueous surfactants is promising to alter steam flow but has yet to be tested and simulated under SAGD conditions The mechanistic population balance method for describing foam flow was extended to a local equilibrium framework that reduces computational costs and is promising for simulation of the effects of foamed steam in 3D **Supporting Technology for Enhanced Oil Recovery - Steamflood Predictive Model** United States.
