A Solution to the Ecological Inference Problem: Reconstructing Individual Behavior from Aggregate Data

Ecological Inference in Public Health

MICHAEL A. STOTO, PhD

A public health official finds a high correlation across health districts between the infant mortality rate and the proportion of the population that is black. Does this mean that an individual black child has less chance of surviving his or her first year? Or suppose there is a negative correlation between hospitalizations for asthma and the proportion of children covered by health insurance. Does this prove that health insurance can help prevent the progression of asthma?

Although questions of this sort have been central to public health from its beginnings, scientists have long been wary of such "ecological inferences." Gary King's new book points out that political scientists and others have faced the same problems

for many years, and he develops a new set of statistical techniques for drawing proper inferences from aggregate data.

Professor King's central idea can be understood through the following example (using his numbers in a public health context). Suppose you know that the infant mortality rate is 19 per 1000 in District A and that 88% of the population is black. With only these two numbers, can anything be said about the infant mortality rate in black children in District A? In other children in the District? King points out that the aggregate rates set limits on the component rates. In this example, the math dictates that the black rate be between 7 per 1000 and 21 per 1000. If, for instance, the black rate were greater than 21, the rate in non-black children would have to be less than zero to get an overall rate of 19.

The overall infant mortality rate (A) is the weighted average of the rate among blacks (B) and non-blacks (C), with the weights being X (the proportion black) and $1-X$. If A is 19/1000 or 0.019, and X is 0.88, then the equation that must be satisfied is $0.019 = 0.88(B) + 0.12(C)$. If C is 0.0, the lowest it could theoretically be, B would have to be $0.019/0.88 = 0.21$. If you did the same thing for $C = 1.0$, you get $A = 0.007$.

Although this doesn't seem to tell us much about District A, when it is combined with similar information about other districts, much

stronger, statistically valid inferences are possible. In *A Solution to the Aggregate Inference Problem*, King develops detailed statistical methods that can be used to refine the inferences that can be drawn from aggregate data. The book carefully lays out the statistical problems, reviews a variety of approaches that have been developed in the past to deal with them, and describes King's own approach to these problems. This approach is innovative and technically appropriate.

King's model requires specialized statistical software, and he has generously made it available to all (along with sample datasets) on his World Wide Web site at gking.harvard.edu. As with any statistical technique, assumptions are necessary, but King's seem minimal. His software includes diagnostic plots that allow the user to review the model's assumptions and fit.

The many examples in King's book, such as voter turnout rates by racial categories, reflect his own background in political science. The independent variables are not too far from those seen in public health, however, so the examples shouldn't be difficult for readers with a public health background. Although it contains deep statistical concepts, the book is written in a mostly non-mathematical way. One result is that a substantial proportion of the text is devoted to explicating the mathematical and statistical concepts motivating and underlying King's methods (and showing us how groundbreaking
