

- After the microprocessor has performed its tasks, the digitized signal must be converted back to its analog equivalent. This is accomplished at the digital to analog (D/A) conversion stage.
- When the digitized signal is converted to its analog stage, it is frequency filtered again, to prevent signal distortion. It is then amplified in the conventional manner and submitted to the receiver (speaker) of the hearing aid.
- For some of the more recent DSP systems, the D/A conversion does not require a separate circuit. Rather, it uses the hearing aid receiver to accomplish digital to analog conversion. This process is referred to as a Direct Digital Drive.
- The obvious advantage of digital signal processing is that there are unlimited ways in which the signal can be manipulated. The number of parameters that can be utilized, at the same instant in time, are significantly greater than those found in conventional analog systems. As such, the ability to manipulate the signal to more closely approximate the acoustic needs of the patient is greatly enhanced.

- Fig: In a further stage of signal processing in hearing aids, the amplitude-range may be compressed. Hence, the gain of the system is progressively reduced when the sound-volume exceeds a specified level. A small delay in adapting the gain to the signal-levels may also be added, as the average of the most recent amplitudes drives the gain control
