Abstract

Byers-Heinlein et al. (2021) argue that a greater focus on reliability in infant research is much needed and desirable for the field. Moreover, they offer a number of possible solutions to increase reliability in infant research. Here, I do not discuss the suitability of the offered solutions. Instead, I further develop the authors' argument by considering the worryingly downstream consequences of low reliability for the very possibility of drawing meaningful inferences from the results of replication studies. I argue that the sources of error related to sampling and measurement greatly affect the estimates, resulting in confidence intervals being often very wide. Consequently, interpreting the differences between small-scale original and replication studies becomes a meaningless task, which, I maintain, could be replaced by a meta-analytic mindset and the habit of fully incorporating uncertainty in the reasoning about research findings.

KEYWORDS

infancy, measurement error, meta-analysis, methodology, replicability

A major problem affecting infant research is certainly the use of small sample sizes and tests with low statistical power. In the target article, Byers-Heinlein et al. (2021) convincingly showcase how the statistical power of a test can be increased independently of sample numerosity by improving reliability. In doing so, they are calling our attention to an aspect that they diagnose to be often neglected by infant researchers: measurement reliability. Because, I suspect, especially in the study of infant cognition much focus has been placed on inferring whether at a certain point in the child's development a certain ability is present or absent, and less focus has been placed on investigating
