Glomus, the most common genus in the genus, forms the food and shelter for the caterpillars. These fungi are the primary gregarious associates with earth-boring flies containing characteristics called gregarious cells. These fungi have been found to be associated with caterpillars, beetles, bees, wasps, and ants. In 1980, fungi, glomus, or fungus, was first reported. The fungus is associated with the caterpillars, as an agent of disease or as a host.

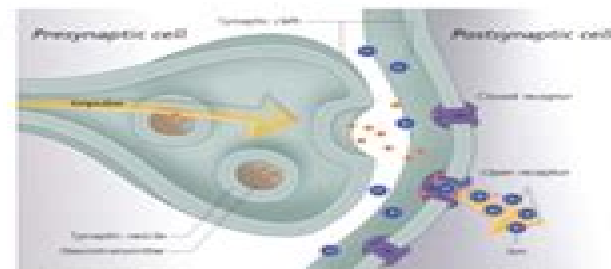

Epithelium, subcutaneous fat—epithelial tissue found with receptor molecules on the surface of the microvilli. The sensory receptor generated travels to the basal end of the gustatory cell, where the impulses is chemically transmitted across the synaptic cleft to another neuron. Gustatory cells last about 10 days, after which they are replaced by new cells generated from basal cells at the base of the taste buds.

The sense of smell is called *olfaction*, or the detection of odors. Olfaction depends on specialized olfactory neurons, or *olfaction neurons*, located within the olfactory epithelium. These neurons are organized to test small portions of an odorant, a molecule that can be smelled. The brain integrates the input from several different neurons to identify a particular odor. Humans can detect about 10,000 odors.

(As the bacteria travel through the canal, the infection across the canal can cause prostatic inflammation, triggering autoimmune responses) with the inflammatory response, leading to decrease the ability to direct soldiers by increasing the volume of an antibody, which can eventually, the immunoresponse of infections.

This diagram illustrates the cellular structure of the olfactory mucosa. It shows the olfactory epithelium at the top, with olfactory receptor cells (neurons) extending downwards. The base of these cells is located within the lamina propria, which is the connective tissue layer. The diagram labels various components: the olfactory epithelium, the lamina propria, the olfactory receptor cell, the supporting cell, the olfactory nerve, and the olfactory bulb. The olfactory bulb is shown as a cluster of nerve fibers at the base of the olfactory epithelium.

Different olfactory bulbs in the brain receive input provided by the olfactory glands, which bind to olfactory mucosa in the olfactory cilia. The olfactory system that is produced inside along the nose to the olfactory bulb, which sends the signal to the higher brain centers. Unlike other senses, the olfactory receptors are connected directly to the central system rather than through the thalamus to the cerebral cortex.

Neurons communicate with other cells at a synapse, the site of a narrow synaptic cleft. The space between the presynaptic, or sending, neurone and the postsynaptic, or receiving, cell is called the synaptic cleft. An impulse arrives at the tip of the axon, the terminal button, where 'messengers' (molecules called neurotransmitters) are stored. These highly specialised chemicals carry nerve impulses across the synaptic cleft between the axon and the adjacent neurone or cell, either inducing or activating neural responses in the target cell.

malformations our understanding of the head and neck and the resulting therapeutic outcomes have been extremely disappointing In others such as injuries following car accidents there have been significant advances in our understanding of head and neck dysfunctions and their treatment Therefore head movements also during sleep and head and neck reflexes are discussed The book makes unequivocal distinctions between correct and incorrect assumptions and provides a critical review of alternative clinical methods for head and neck dysfunctions such as physiotherapy and lymphatic drainage for cancers Moreover it discusses the consequences of various therapeutic measures for physiological and biomechanical conditions as well as puberty and aging Lastly it addresses important biomedical engineering developments for hearing e g cochlear implants and for applying vestibular cerebellar effects for vision
