

Efforts to devise vaccines and new treatments for HIV depend on knowledge of the virus's life cycle. HIV invades host cells and commandeers their machinery to make more copies of itself. First, a protein called *envelope* on the virus must bind to CD4 and CCR5 proteins on the cell surface (1). As the virus fuses with the cell, it empties its contents into the cytoplasm (2). A viral enzyme, reverse transcriptase, then copies the virus's RNA genome into double-stranded DNA (3), often making errors that generate diversity in the virus copies. Another viral enzyme, *Integrase*, inserts the copy into

the host DNA (4). Cell machinery transcribes the viral genes back into RNA (including RNA that can serve as templates for proteins) that travels to the cytoplasm, where ribosomes produce the encoded proteins (5). Viral RNA and proteins then move toward the cell membrane, where they gather into a budding virus particle (6). In the immature new virus copy, the HIV protease enzyme modifies viral protein chains, enabling the particles, or virions, to mature into a form that is ready to infect a new cell (7).
