Spinal Cord Plasticity Alterations In Reflex Function:

Spinal Cord Plasticity Michael M. Patterson, James W. Grau, 2011-06-28 The area of spinal cord plasticity has become a very actively researched field The spinal cord has long been known to organize reflex patterns and serve as the major transmission pathway for sensory and motor nerve impulses However the role of the spinal cord in information processing and in experience driven alterations is generally not recognized With recent advances in neural recording techniques behavioral technologies and neural tracing and imaging methods has come the ability to better assess the role of the spinal cord in behavioral control and alteration The discoveries in recent years have been revolutionary Alterations due to nociceptive inputs simple learning paradigms and repetitive inputs have now been documented and their mechanisms are being elucidated These findings have important clinical implications The development of pathological pain after a spinal cord injury likely depends on the sensitization of neurons within the spinal cord The capacity of the spinal cord to change as a function of experience and adapt to new environmental relations also affects the recovery locomotive function after a spinal cord injury Mechanisms within the spinal cord can support stepping and the capacity for this behavior depends on behavioral training By taking advantage of the plasticity inherent within the spinal cord rehabilitative procedures may foster the recovery of function

Petruska, Charles Hubscher, 2015-01-05 Traumatic injury of the spinal cord affects the entire organism directly and indirectly Primary injury destroys neurons and severs axons which participate in neural circuits Secondary injuries and pathologies arise from numerous sources including systemic inflammation consequential damage of cutaneous muscular and visceral tissues and dysregulation of autonomic endocrine and sensory motor functions Evidence is mounting that spinal cord injury SCI affects regions of the nervous system spatially remote from the injury site as well as peripheral tissues and alters some basic characteristics of primary afferent cell biology and physiology cell number size frequency electrophysiology other The degree of afferent input and processing above the lesion is generally intact while that in the peri lesion area is highly variable though pathologies emerge in both regions including a variety of pain syndromes Primary afferent input to spinal regions below the injury and the processing of this information becomes even more important in the face of complete or partial loss of descending input because such spared sensory processing can lead to both adaptive and pathological outcomes This issue

hosts review and research articles considering mechanisms of plasticity of primary afferent neurons and sensory processing after SCI and how such plasticity contributes to sparing and or recovery of functions as well as exacerbation of existing and or emergent pathologies A critical issue for the majority of the SCI community is chronic above and below level neuropathic pain much of which may arise at least in part from plasticity of afferent fibers and nociceptive circuitry For example autonomic dysreflexia is common hypertensive syndrome that often develops after SCI that is highly reliant on maladaptive nociceptive sensory input and processing below the lesion Moreover the loss of descending input leaves the reflexive components of bladder bowel sexual function uncoordinated and susceptible to a variety of effects through afferent fiber plasticity Finally proper afferent feedback is vital for the effectiveness of activity dependent rehabilitative therapies but aberrant nociceptive input may interfere with these approaches since they are often unchecked due to loss of descending modulation
