*Embedded Processor-Based Self-Test* Dimitris Gizopoulos, A. Paschalis, Yervant Zorian, 2013-03-09. *Embedded Processor Based Self Test* is a guide to self testing strategies for embedded processors. Embedded processors are regularly used today in most System on Chips, SoCs. Testing of microprocessors and embedded processors has always been a challenge because most traditional testing techniques fail when applied to them. This is due to the complex sequential structure of processor architectures which consists of high performance datapath units and sophisticated control logic for performance optimization. Structured Design for Testability, DfT, and hardware based self testing techniques which usually have a non trivial impact on a circuit's performance, size, and power, can not be applied without serious consideration and careful incorporation into the processor design. *Embedded Processor Based Self Test* shows how the powerful embedded functionality that processors offer can be utilized as a self testing resource. Through a discussion of different strategies, the book emphasizes on the emerging area of Software Based Self Testing, SBST. SBST is based on the idea of execution of embedded software programs to perform self testing of the processor itself and its surrounding blocks in the SoC. SBST is a low cost strategy in terms of overhead, area, speed, power, development effort, and test application cost, as it is applied using low cost, low speed test equipment. *Embedded Processor Based Self Test* can be used by designers, DfT engineers, test practitioners, researchers, and students working on digital testing and in particular processor and SoC test. This book sets the framework for comparisons among different SBST methodologies by discussing key requirements. It presents successful applications of SBST to a number of embedded processors of different complexities and instruction set architectures.

*The Core Test Wrapper Handbook* Francisco da Silva, Teresa McLaurin, Tom Waayers, 2006-09-15 In the early to mid 1990 s while working at what was then Motorola Semiconductor business changes forced my multi hundred dollar microprocessor to become a tens of dollars embedded core I ran into first hand the problem of trying to deliver what used to be a whole chip with something on the order of over 400 interconnect signals to a design team that was going to stuff it into a package with less than 220 signal pins and surround it with other logic I also ran into the problem of delivering microprocessor specification verification a microprocessor is not just about the functions and instructions included with the instruction set but also the MIPS rating at some given frequency I faced two dilemmas one I could not deliver functional vectors without significant development of off core logic to deal with the reduced chip I/O map and everybody's I/O map was going to be a little different and two the JTAG 1149.1 boundary scan ring that was around my core when it was a chip was going to be woefully inadequate since it did not support speed signal application and capture and independent use separate from my core I considered the problem at length and came up with my own solution that was predominantly a separate non JTAG scan test wrapper that supported at speed application of launch capture cycles using the system clock But my problems weren't over at that point either
