

very detailed discussion, although the use, for example, of probable errors has a slightly archaic ring about it. A statistician must deplore the apparent failure of statistical thinking over the past quarter of a century to make any impression on at least one group of scientists. (The only statisticians referred to by the author are Gauss, Laplace and Karl Pearson.) It may be that a more sophisticated approach is unnecessary for astronomers, and within the chosen limits the presentation is clear and thorough, if a trifle dogmatic.

The contents include: frequency distributions, the method of least squares, probability, the Normal law, measures of precision, equations of condition (the least squares solution of n equations in m unknowns when $n > m$), theoretical frequency distributions, correction of statistics and correlation; finally there are four short tables, including one of $\text{erf } t$.

Studies in the Mathematical Theory of Inventory and Production. By K. J. ARROW, S. KARLIN and H. SCARF. Pp. x, 340. 70s. 1958. (Stanford University Press; O.U.P., London)

All but one of this excellent collection of seventeen research papers was written, at least in part, by the named authors, and all these papers are here published for the first time. The volume is concerned with various mathematical models which have been put forward as representing storage systems, and the papers range from a historical survey, through optimal policies in both deterministic and stochastic storage systems, to more detailed consideration of the properties of the models for these and analogous systems.

It may be remarked that the previous occasion, on which mathematicians and economists showed interest in this subject, was in the decade immediately preceding the depression of the 1930's. It is to be hoped this was a coincidence.

Finite Queuing Tables. By L. G. PECK and R. N. HAZELWOOD. Pp. xvi, 210. 68s. 1958. (John Wiley, New York; Chapman and Hall, London)

The type of problem, for which these tables offer a solution, is as follows: N automatic machines each stop running independently and at random instants of time, the average rate of breakdown being $1/U$ per machine. M operators look after these machines and the time taken for an operator to restart a machine has an exponential distribution with mean T . $X = T/(T + U)$, the service factor, is a measure of the reliability of the machine. A system defined in these terms may be regarded as a finite queue (of machines waiting to be serviced) and the properties of this queue in statistical equilibrium are completely determined by N , M and X .

The quantities tabulated here (to 3 decimal places) are D , the probability that in equilibrium a defective machine may have to wait before
