## Taste & Smell

### Taste & smell

Most of our special senses are chemoreception systems: gustation (taste) and olfaction (smell). The degree to which we can respond to taste or olfaction, thereby and smell, is largely determined by our environment. In fact, olfaction, thereby and smell, is largely determined by our environment. In fact, olfaction, thereby and smell, is largely determined by our environment. In fact, olfaction, thereby and smell, is largely determined by our environment.

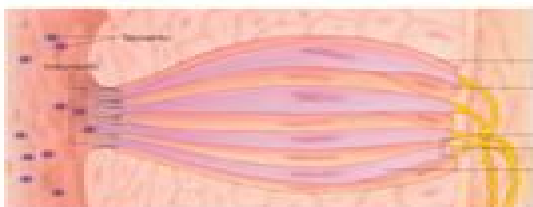

### Concentrations

Taste receptors vary depending on the concentration of substances in a given solution or food. For low concentrations, taste is weak and salty substances may taste bitter.

### Gustation

Gustation, the sense of taste, gives us information about the food and drink that we consume. Taste buds on the primary gustatory organ, the tongue, contain chemoreceptors called gustatory cells. These taste buds have four basic components: sweet, salty, bitter, and umami. A fifth taste, glutamate or savory, has been reported. This flavor is associated with umami, an amino acid in meat, fish, and cheese.

### The taste bud

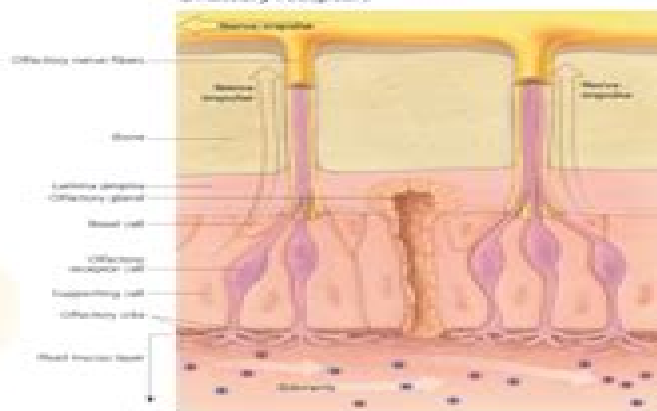

Each taste bud contains gustatory cells that have receptor molecules on the surface of the microvilli. The resulting receptor potential travels to the basal end of the gustatory cell, where the signal is chemically transmitted to the afferent nerve via a chemical synapse. Gustatory cells live about 10 days, after which they are replaced by new cells generated from basal cells at the base of the taste bud.

### Olfaction

The sense of smell is called olfaction, or the detection of odors. Olfaction depends on specialized chemical receptors, or chemoreceptors, located within the olfactory epithelium. These receptors are designed to respond to small amounts of an odorant, a molecule that can be smelled. The brain integrates the input from several different receptors to identify a particular odor. Humans can detect about 10,000 odors.

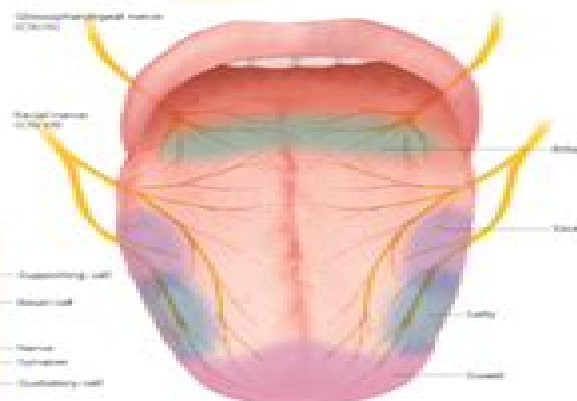

As air flows through the nose, the odors across the nasal cavity pass over the olfactory epithelium. Incoming odorant molecules can interact with the olfactory neurons, leading to the ability to detect odors by increasing the release of an impulse, which can activate the neurons of the brain.

### Olfactory receptors

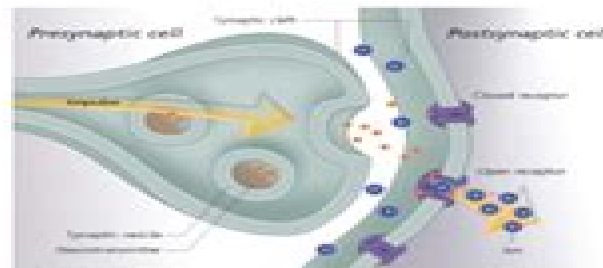

### Olfactory receptors

Olfactory receptors in the olfactory epithelium are produced by the olfactory gland. These glands produce olfactory molecules on the olfactory cells. The olfactory potential that is generated travels along the axon to the olfactory bulb, where it meets the input to the higher brain centers. Unlike other senses, the olfactory neurons are connected directly to the cerebral cortex, rather than through the thalamus in the cerebrum.

Compound sweet and salty tastes, we are 100 times more sensitive to taste compounds than about 1,000 times more sensitive to salty tastes. This is because a small taste, when it is in a large amount, can be detected. And many tastes can be detected. Typically, an adult can taste about 10,000 tastes. But, the number decreases as we age.

### The synapse

Neurons communicate with other cells at a synapse, the site of a nerve impulse transmission. The space between the presynaptic, or sending, neuron and the postsynaptic, or receiving, cell is called the synaptic cleft. An impulse enters at the tip of the axon, the axon hillock, where "trigger" molecules called neurotransmitters. These highly specialized chemicals carry nerve impulses from the presynaptic cell to the postsynaptic cell. The impulse enters the cell, where it is released into the synaptic cleft, where it is released into the synaptic cleft, where it is released into the synaptic cleft.
