Technologies for Prospecting, Extraction, and Utilization of Space Resources Paul Zabel, Philipp Reiss, Angel Abbud-Madrid, Beth Lomax, Florian Kehl, Valentin T. Bickel, Hendrik Kolvenbach, Philip Arm, Gabriela Ligeza, 2024-11-18

Sustainable exploration of the solar system requires a large amount of material and propellant to be transported out of Earth's gravity well and onwards to their destination. Despite recent advances in lowering launch costs, transferring material from Earth to space is still very costly. It still amounts to several thousand to tens of thousands of Euros per kilogram to low Earth orbit and transportation to the Moon and Mars, even a multiple of that. There is an abundance of resources in our solar system that can be utilized to reduce the material required to be launched from Earth significantly. Among these resources are water, ice, hydrates, metals, regolith, rare earth elements, chemical compounds, volatiles, and rare isotopes. Utilizing these space resources would enable, e.g., consumable and propellant production in space, manufacturing, or the construction of large structures which would otherwise be very expensive or not possible at all with material launched from Earth. Lunar regolith, for example, contains iron and titanium that could be used to produce spacecraft components or structural elements for a lunar base, while oxygen released from oxide minerals could be used for respiration or as a propellant. In addition, water ice could be extracted from regolith and used for consumption or agricultural applications. Although there have been numerous missions to the Moon, there are still a lot of unknowns concerning its surface, making it difficult to know where to look for resources and how to extract them.
