Tumors of the Testis and Adjacent Structures Thomas M. Ulbright, Robert H. Young, American Registry of Pathology, 2013 This edition represents a significant expansion of both the textual and illustrative material of the previous volume The numerous images reflect the authors belief that the atlas role that was the intent of the original edition is of paramount importance in this work At the same time the current scope is no longer primarily that of a visual resource but also a comprehensive guide to clinical pathologic immunohistochemical molecular biologic prognostic and to a limited extent therapeutic aspects of the various entities For this reason the authors have greatly expanded coverage of the immunohistochemical and molecular features of the various lesions recognising that such information is quickly supplemented by new observations Nonetheless they continue to believe that careful gross examination and routine light microscopic observations are the foundations for diagnosis of these neoplasms and neoplastic like processes A complement to Tumors of the Prostate Gland Seminal Vesicles Penis and Scrotum this volume will serve as an outstanding resource for the diagnosis of testicular neoplasms for pathologists at all levels of experience

Pavone-Macaluso, 2014-09-01 *Testis cancer: genes, environment, hormones* Alberto Ferlin, Carlo Foresta, 2015-10-29

Testicular cancer TC is the most common cancer in males aged 20 40 years with a worldwide incidence of 7.5 per 100 000 but the rates vary considerably between countries and ethnic groups and there is evidence also for an increasing incidence in last decades About 95% of all TCs are represented by testicular germ cell tumors TGCTs which include seminoma and non seminoma histological types It is generally assumed that the development of TGCT is under endocrine control In particular unbalanced androgen estrogen levels and or activity are believed to represent the key events for TGCT development and progression Furthermore recent evidence has suggested genetic association of TGCT with variations in genes involved in hypothalamic pituitary testicular axis and steroidogenic enzymes This recent evidence expands the current knowledge on the role of genetic contribution in testicular cancer susceptibility and supports the hypothesis that variations in hormone metabolism genes might change the hormonal environment implicated in testicular carcinogenesis Therefore hormonal carcinogenesis is an important and controversial area of current research in TGCT and further attention is given to genetic factors influencing hormone related cancer risk The genetic component to TGCT is in general strong In fact although environmental factors clearly contribute to TGCT development and probably to its increasing incidence in some geographical areas the proportion of TGCT susceptibility accounted for by the genetic effects is estimated at 25% TGCT has high familial risks compared with most other cancer types that are generally no more than two fold brothers of individuals with TGCT have an 8 to 12 fold increased risk of disease and sons of affected individuals have a 4 to 6 fold increased risk Despite this strong familial relative risk early results from linkage studies identified a limited relationship with genetic factors suggesting that TGCT is a genetically complex trait However more recently four genome wide association studies GWAS from the UK and USA have reported association of TGCTs with six new loci KITLG SPRY4 BAK1 DMRT1 TERT and ATF7IP The strongest association for TGCT susceptibility was found for SNPs in KITLG ligand for the membrane bound receptor tyrosine kinase KIT gene with a greater than 2.5 fold increased risk of disease per major allele which is the highest reported for any cancer to date These studies are being now replicated by other researches and attention is given to the relationship between these genetic variations TGCT risk and frequently associated anomalies of the reproductive tract such as cryptorchidism and infertility Finally over the past few decades TCGT research has focused also on external environmental causes acting mainly as endocrine disruptors of androgen and oestrogen pathways even during the foetal development of the testis It is well known that the testicular dysgenesis syndrome TDS hypothesis proposed ten years ago suggests that disturbed testicular development in fetal life may result in one or more of four disorders postnatally named cryptorchidism hypospadias poor semen quality and TGCT These four disorders are therefore considered as one clinical entity and are linked together by epidemiological and pathophysiological relations The relative contribution of genetics and environment in TGCT development and the interactions between endocrine disruptors and variations in genes involved in hormonal carcinogenesis is therefore another interesting area of research

Testicular Cancer, An Issue of Urologic Clinics Daniel W. Lin, 2015-07-29 This

Carcinoma of the Kidney and Testis, and Rare Urologic Malignancies Zbigniew Petrovich, Luc Baert, Luther W. Brady, 2013-11-11 In the United States in 1997 28800 new cases of malignant tumors of the kidney and renal pelvis were diagnosed along with 2100 new cases of malignant tumors of the ureter and other urinary organs 7200 primary malignant tumors of the testis and 1300 primary malignant tumors of the penis and other genital organs In large measure surgery is the treatment of choice for these tumors but radiation therapy is increasingly recognized as having significant and important curative and palliative benefits in each of these tumor sites Surgery is the standard form of treatment for non metastatic renal cell carcinomas as well as for malignancies of the renal pelvis and ureter with radical nephrectomy and radical uretectomy being employed However postoperative radiation therapy is of value for those patients who demonstrate evidence of residual tumor following surgery transection of tumor during surgery or positive regional lymph node drainage As regards the rare tumors that involve the female urethra surgical resection is appropriate for those that are limited and local in character and amenable to partial uretectomy With tumors that are more advanced in character however local recurrence and lymphatic dissemination are significant problems and treatment by radiation therapy programs alone yield satisfactory control rates as well as limited recurrences and long term survivors For primary tumors involving the testis the major approach to nonseminomatous tumors is surgical resection with postsurgical systemic chemotherapy
