

Chromosomes

The cell nucleus contains the majority of the cell's genetic material, in the form of multiple linear DNA molecules organized into structures called chromosomes. During most of the cell cycle these are organized in a DNA-protein complex known as chromatin, and during cell division the chromatin can be seen to form the well defined chromosomes familiar from a karyotype. A small fraction of the cell's genes are located instead in the mitochondria.

There are two types of chromatin: *euchromatin* is the less compact DNA form, and contains genes that are frequently expressed by the cell.^[10] The other type, *heterochromatin*, is the more compact form, and contains DNA that are infrequently transcribed. This structure is further categorized into *facultative heterochromatin*, consisting of genes that are organized as heterochromatin only in certain cell types or at certain stages of development, and *constitutive heterochromatin* that consists of chromosome structural components such as telomeres and centromeres.^[10]

During interphase the chromatin organizes itself into discrete individual patches,^[10] called *chromosome territories*.^[11] Active genes, which are generally found in the euchromatic region of the chromosome, tend to be located towards the chromosome's territory boundary.^[12]

Antibodies to certain types of chromatin organization, particularly nucleosomes, have been associated with a number of autoimmune diseases, such as systemic lupus erythematosus.^[22] There are known as anti-nuclear antibodies (ANAs) and have also been observed in context with multiple sclerosis as part of general immune system dysfunction.^[22] As in the case of prionin, the role played by the antibodies in inducing the symptoms of autoimmune diseases is not obvious.

Nucleolus

An electron micrograph of a cell nucleus, showing the darkly stained nucleolus.

A human fibroblast nucleus in which DNA is stained blue. The distinct chromosome territories of chromosome 2 (red) and chromosome 9 (green) are visible, stained with fluorescent in situ hybridization.

The nucleolus is a discrete densely stained structure found in the nucleus. It is not surrounded by a membrane, and is sometimes called a *suborganelle*. It forms around tandem repeats of rDNA, DNA coding for ribosomal RNA (rRNA). These regions are called nucleolar organizer regions (NORs). The main roles of the nucleolus are to synthesize rRNA and assemble ribosomes. The structural cohesion of the nucleolus depends on its activity, as ribosomal assembly in the nucleolus results in the transient association of nucleolar components, facilitating further ribosomal assembly, and hence further association. This model is supported by observations that inactivation of rDNA results in intermingling of nucleolar structures.^[10]

The first step in ribosomal assembly is transcription of the rDNA, by a protein called RNA polymerase I, forming a large pre-rRNA precursor. This is cleaved into the subunits 5.8S, 18S, and 28S
