## The urinary system

The urinary system is responsible for three major functions in the body: removing wastes, removing excess water, and controlling acid-base balance in the blood. The individual components of the urinary system, kidneys, ureters, bladder, and urethra, each play an important role in these processes.

Urine formation begins within the functional units of the kidneys called **nephrons**. In nephrons, there are processes of filtration, reabsorption, and secretion. Secretion involves moving substances out of capillaries and into the general body fluid. Filtration involves moving substances out of capillaries and into the general body fluid. Secretion involves moving substances out of capillaries and into the general body fluid.

## The kidney

The kidneys are located on each side of the spine in the back of the abdominal cavity. Each kidney is approximately 10 cm long and weighs about 150 grams. The outer layer is called the **capsule**, which is covered by a layer of fat called the **adipose capsule**.

Within the kidney are two main regions. The **cortex** is the outer layer, which contains the **nephrons**. The **medulla** is the inner layer, which contains the **collecting ducts**. The **renal pelvis** is the part of the kidney that leads to the **ureter**.

## The nephron

Each kidney contains more than a million nephrons. The **nephron** is the functional unit of the kidney. It is a single nephron is made up of two components: the **renal corpuscle**, the proximal convoluted tubule, the loop of Henle, and the distal convoluted tubule.

## Filtration

Substances move through the glomerular capillary filtration barrier into a fluid called **filtrate**. Blood and filtrate move through the **filtrate** barrier. There are three parts to the barrier: the **endothelial wall**, the **basement membrane**, and the **glomerular capillary**. The **endothelial wall** is the outermost layer. The **basement membrane** is the middle layer. The **glomerular capillary** is the innermost layer.

The **filtrate** consists of the **filtrate** substances in the **filtrate** barrier. The **filtrate** substances are the **filtrate** substances in the **filtrate** barrier. The **filtrate** substances are the **filtrate** substances in the **filtrate** barrier.

## Filtrate formation in the nephron

## How urine is produced

The kidneys produce an average of 1.5L of urine per day. Urine is produced by the **nephrons**. The **nephrons** are the functional units of the kidney. The **nephrons** are the functional units of the kidney.

## The composition of urine

## Key stages of urine formation

- Filtration** - Filtration of water, waste products, sodium, glucose and other chemicals.
- Reabsorption** - Movement of usable substances back to the bloodstream.
- Secretion** - Transport of waste materials from capillaries around the renal tubule back into the distal tubule for removal with the urine.

## ADH and fluid levels

## ADH & fluid volume

ADH, or **antidiuretic hormone**, decreases the permeability of the collecting ducts. ADH decreases the permeability of the collecting ducts. ADH decreases the permeability of the collecting ducts.
