Lacrimal Gland, Tear Film, and Dry Eye Syndromes 2 David A. Sullivan, Darlene A. Dartt, Michele A. Meneray, 2012-12-06
During the past two decades a significant international research effort has been directed toward understanding the composition and regulation of the preocular tear film. This effort has been motivated by the recognition that the tear film plays an essential role in maintaining corneal and conjunctival integrity, protecting against microbial challenge and preserving visual acuity. In addition, research has been stimulated by the knowledge that alteration or deficiency of the tear film, which occurs in countless individuals throughout the world, may lead to desiccation of the ocular surface, ulceration and perforation of the cornea, an increased incidence of infectious disease and potentially pronounced visual disability and blindness. To promote further progress in this field of vision research, the Second International Conference on the Lacrimal Gland Tear Film and Dry Eye Syndromes: Basic Science and Clinical Relevance was held at the Southampton Princess Resort in Bermuda, November 16-19, 1996. This conference was organized and directed by David A. Sullivan, Ph.D., codirected by Darlene A. Dartt, Ph.D., and Michele A. Meneray, Ph.D., and sponsored by the Schepens Eye Research Institute, Boston, MA, an affiliate of Harvard Medical School. The meeting was designed to assess critically the current knowledge and state of the art research on the structure and function of lacrimal tissue, tears and the ocular surface in both health and disease.

This meeting was designed to assess critically the current knowledge and state of the art research on the structure and function of lacrimal tissue and tears in both health and disease. The goal of this conference was to provide an international exchange of information that would be of value to basic scientists involved in eye research, to physicians in the ophthalmological community and to pharmaceutical companies with an interest in the treatment of lacrimal gland tear film or ocular surface disorders, e.g., Sjögren's syndrome.

The Optical Effects of Tear Film Disruption Ronald Cogswell, 1999
The most

anterior optical surface of the eye has the greatest refractive power Therefore the quality of this surface is critical to retinal image quality and visual performance Most optical texts identify the cornea as the first optical surface but in fact it is the tear layer A smooth tear layer is considered optically essential and superior to the microscopically irregular corneaZ epithelium Unlike the other optical surfaces within the eye the tear film can vary tremendously from second to second as tear film changes occur between blinks Although numerous studies have evaluated the change in tear film quality during periods of non blinking little is know about the optical and visual effects resulting from changes in the tear film layer The classic tear film models suggest that the precorneal tear film is composed of three layers the superficial lipid layer derived from the meibomian glands the middle aqueous layer provided by the major and minor lacrimal glands maintains ocular wetting among other physiological effects and the inner most layer overlies the corneaZ and conjunctival epithelial cells with mucous like material Recent studies suggest that the tear film is composed of a mucin gel topped by a thin lipid film **Lacrimal**
