The Functional Analysis Of Lignins And Their Derivatives:

Functional Analysis of Lignins and Their Derivatives Girt Fritsevich Zakis,1994-01-01 **Biomass Modification, Characterization and Process Monitoring Analytics to Support Biofuel and Biomaterial Production** Robert Henry,Blake Simmons,Jason Lupoi,2016-06-09

The conversion of lignocellulosic biomass into renewable fuels and other commodities has provided an appealing alternative towards supplanting global dependence on fossil fuels The suitability of multitudes of plants for deconstruction to useful precursor molecules and products is currently being evaluated These studies have probed a variety of phenotypic traits including cellulose non cellulosic polysaccharide lignin and lignin monomer composition glucose and xylose production following enzymatic hydrolysis and an assessment of lignin carbohydrate and lignin lignin linkages to name a few These quintessential traits can provide an assessment of biomass recalcitrance enabling researchers to devise appropriate deconstruction strategies Plants with high polysaccharide and lower lignin contents have been shown to breakdown to monomeric sugars more readily Not all plants contain ideal proportions of the various cell wall constituents however The capabilities of biotechnology can alleviate this conundrum by tailoring the chemical composition of plants to be more favorable for conversion to sugars fuels etc Increases in the total biomass yield cellulose content or conversion efficiency through for example a reduction in lignin content are pathways being evaluated to genetically improve plants for use in manufacturing biofuels and bio based chemicals Although plants have been previously domesticated for food and fiber production the collection of phenotypic traits prerequisite for biofuel production may necessitate new genetic breeding schemes Given the plethora of potential plants available for exploration rapid analytical methods are needed to more efficiently screen through the bulk of samples to hone in on which feedstocks contain the desired chemistry for subsequent conversion to valuable renewable commodities The standard methods for analyzing biomass and related intermediates and finished products are laborious potentially toxic and or destructive They may also necessitate a complex data analysis significantly increasing the experimental time and add unwanted delays in process monitoring where delays can incur in significant costs Advances in thermochemical and spectroscopic techniques have enabled the screening of thousands of plants for different phenotypes such as cell wall cellulose non cellulosic polysaccharide and lignin composition lignin monomer composition or monomeric sugar release Some instrumental methods have been coupled with multivariate analysis providing elegant chemometric predictive models enabling the accelerated identification of potential feedstocks In addition to the use of high throughput analytical methods for the characterization of feedstocks based on phenotypic metrics rapid instrumental techniques have been developed for the real time monitoring of diverse processes such as the efficacy of a specific pretreatment strategy or the formation of end products such as biofuels and biomaterials Real time process monitoring techniques are needed for all stages of the feedstocks to biofuels conversion process in order to maximize efficiency and lower costs by monitoring and optimizing performance These approaches allow researchers to adjust

experimental conditions during rather than at the conclusion of a process thereby decreasing overhead expenses This Frontiers Research Topic explores options for the modification of biomass composition and the conversion of these feedstocks into biofuels or biomaterials and the related innovations in methods for the analysis of the composition of plant biomass and advances in assessing up and downstream processes in real time Finally a review of the computational models available for techno economic modeling and lifecycle analysis will be presented
