Taste & Smell

Taste & smell

Most of our special senses are chemoreception systems: gustation (taste) and olfaction (smell). The degree to which we can respond to taste or olfaction, thereby, and smell is controlled by the number of receptors in the nose and mouth. The sense of taste is less discriminatory than the sense of smell, and there is an overlap between taste receptors. The sense of smell is highly discriminatory, with several types of olfactory receptors, each responding to particular odors. Taste and olfaction are related to smell, vision and hearing, important with the sense of touch, but taste is particularly affected by the sense of smell.

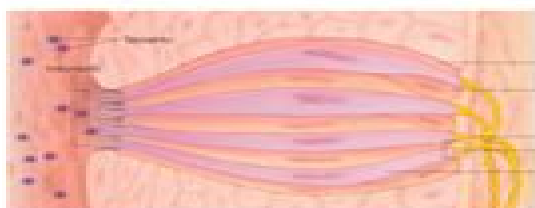

Concentrations

Taste receptors vary depending on the concentration of substances in a given solution or solid. For low concentrations, taste is not as salty, sweet, sour, or bitter as higher concentrations.

Gustation

Gustation, the sense of taste, gives us information about the food and drink that we consume. Taste buds on the primary gustatory organ, the tongue, contain chemoreceptors called gustatory cells. These taste buds have four basic components: sweet, sour, bitter and salty. A fifth taste, umami, or savory, has been reported. This flavor is associated with proteins, or its agent, glutamate or meat broth.

The taste bud

Essential substances that produce taste, food, with receptor molecules on the surface of the microvilli. The resulting receptor potential travels to the basal end of the gustatory cell, where the signal is electrically transmitted to the supporting cell for further processing. Gustatory cells live about 10 days, after which they are replaced by new cells generated from basal cells at the base of the taste buds.

Compound sweet and salty tastes, we are 100 times more sensitive to taste compounds than about 1,000 times more sensitive to taste compounds. This is because a small taste, when it is not too strong, and many compounds can be detected. Typically, an adult can taste about 10,000 compounds. But, the number declines as we age.

Olfaction

The sense of smell is called olfaction, or the detection of odors. Olfaction depends on specialized chemical receptors, or chemoreceptors, located within the olfactory epithelium. These receptors are designed to respond to small amounts of an odorant, a molecule that can be smelled. The brain integrates the input from several different receptors to identify a particular odor. Humans can detect about 10,000 odors.

As air flows through the nose, the odors across the nasal cavity pass through the olfactory epithelium, bringing odorous molecules into contact with the olfactory neurons. Binding increases the ability to detect odors by increasing the volume of air inhaled, which can increase the number of receptors.

Olfactory receptors

Olfactory receptors

Olfactory receptors in the olfactory epithelium are produced by the olfactory gland, then travel to receptor molecules on the olfactory cells. The receptor potential that is generated travels along the axon to the olfactory bulb, where it meets the input to the higher brain centers. Unlike other senses, the olfactory neurons are connected directly to the cerebral cortex, rather than through the thalamus in the cerebrum.

The synapse

Neurons communicate with other cells at a synapse, the site of a nerve impulse transmission. The space between the presynaptic, or sending, neuron and the postsynaptic, or receiving, cell is called the synaptic cleft. An impulse enters at the top of the axon, the terminal bulb, where 'messenger' molecules called neurotransmitters. These highly specialized chemicals carry nerve impulses from the presynaptic cell to the postsynaptic cell. The signal enters the cell, where it is released into the synaptic cleft, where it binds to the postsynaptic cell, where it is released into the synaptic cleft, where it binds to the postsynaptic cell.
