Abstract

Prostate cancer (PCa) is the most common cancer among men in the United States and the second leading cause of cancer-related deaths. Metastatic castration-resistant PCa is still a fatal disease. On the other hand, between 2016 and 2020, about 70% of PCa cases were diagnosed at a localized stage. Evolving data demonstrates that men with low-grade cancers treated with definitive therapies may now be exposed to morbidities of overtreatment and poor quality of life, with little or no benefit in terms of cancer specific mortality. Active surveillance (AS) is thus the recommended management strategy for men with low-grade disease. Although this subgroup of men have reported anxiety during the AS period, they account to be highly motivated to make positive lifestyle changes to further reduce their risk of PCa progression, underscoring the urgent need to identify novel strategies for preventing progression of localized PCa to metastatic disease through pharmacologic means, an approach termed chemoprevention. Although several promising agents and approaches have been examined over the past 2 decades, currently, there are several limitations in the approach used to systematically examine agents for chemoprevention targeting men on AS. The goal of this review is to summarize the current agents and approaches evaluated, targeting men on AS, recognize the gaps, and identify a contemporary and comprehensive path forward. Results of these studies may inform the development of phase III clinical trials and ultimately provide a strategy for clinical chemoprevention in men on AS, for whom, currently, there are no options for reducing the risk of progression to metastatic disease.

Introduction

Prostate Cancer

It is estimated that about 299 010 new cases of prostate cancer (PCa) will be diagnosed in the US in 2024, and 35 250 deaths will occur in men with PCa (ACS 2024).¹ Since the year 2014, the incidence rate of PCa has increased by 3% per year overall and by about 5% per year for advanced-stage PCa. PCa is the most common cancer among men in the US and the second leading cause of cancer-related deaths in the US. Some of the definitive risk factors associated to PCa includes age, genetic predisposition and race.² In 2019, 37% of PCa cases were

Strategies for the Chemoprevention of Prostate Cancer Claude C. Schulman, Gary Kelloff, 1999-01-01 Prostate cancer is a prime target for chemoprevention studies because of its long latency high incidence and known risk factors furthermore hormonal dependency and precursor lesions are well documented To identify suitable populations for evaluation of potential chemopreventive agents and for future chemopreventive intervention risk factors such as the presence of early premalignant lesions and genetic predisposition should be well characterized Therefore identification and characterization of intermediate biomarkers and their validation as surrogate endpoints for cancer incidence in clinical chemoprevention trials are significant components in the development of chemopreventive agents Promising chemopreventive drugs of the prostate include retinoids antiandrogens antioestrogens steroid aromatase inhibitors 5a reductase inhibitors vitamins D and E selenium lycopene and 2 difluoromethylomithine As a new concept in prostate cancer chemoprevention should have a significant impact in the future on the incidence and mortality of this leading cancer threat in men **Current Aspects in**
