

Beginner's Guide - Unix Socket Tutorial

Communication between two distinct processes running on the same or different machines is made possible by sockets. It's a method of communicating with other computers utilizing common Unix file descriptors, to be more precise. Every I/O operation in Unix is carried out by writing to or reading from a file descriptor. An open file is simply identified by a file descriptor, which can be a network connection, a text file, a terminal, or something else entirely.

For a programmer, a socket resembles a low-level file descriptor in both appearance and behavior. This is due to the fact that operations like `read()` and `write()` operate on sockets in the same manner as they do on files and pipes.

Sockets were first introduced in 2.1BSD and subsequently refined into their current form with 4.2BSD. The sockets feature is now available with most current UNIX system releases.

Where is Socket Used?

A client-server application architecture employs a Unix Socket. A server is a program that responds to a client's request by carrying out specific tasks. Sockets are used by the majority of application-level protocols, including FTP, SMTP, and POP3, to create connections between clients and servers and later for data exchange.

Socket Types

Users have access to four different types of sockets. The last two are infrequently used, while the first two are most frequently used.

There is no constraint that inhibits communication between sockets of various types, despite the presumption that processes will only interact with sockets of the same type.

- **Stream Sockets** – Delivery in a networked environment is guaranteed. If you send through the stream socket three items "A, B, C", they will arrive in the same order – "A, B, C". These sockets use TCP (Transmission Control Protocol) for data transmission. If delivery is impossible, the sender receives an error indicator. Data records do not have any boundaries.
- **Datagram Sockets** – Delivery in a networked environment is not guaranteed. They're connectionless because you don't need to have an open connection as in Stream Sockets – you build a packet with the destination information and send it out. They use UDP (User Datagram Protocol).
- **Raw Sockets** – These provide users access to the underlying communication protocols, which support socket abstractions. These sockets are normally datagram oriented, though their exact characteristics are dependent on the
