Advances in Understanding Thermal Effects in Rubber Gert Heinrich, Reinhold Kipscholl, Jean-Benoît Le Cam, Radek Stoček, 2024-09-10 In the case of an ideal rubber one often thinks of the linear dependence of the shear modulus on temperature as an expression of the typical entropy elasticity However temperature dependencies of typical technical rubber materials are known to be much more complicated This has consequences for the practical behaviour of rubber elastic components One well known instance of this is the dramatic Challenger disaster The rubber used to seal the solid rocket booster joints with O rings did not expand at temperatures of 0 °C or below resulting in an opening in the solid rocket booster joint through which gas attempted to escape The main physical reason for the heat generation processes is the hysteresis of rubber materials due to deformation and viscoelasticity Most elastomers therefore change significantly over time when exposed to heat and likewise light or oxygen ozone These changes can have a dramatic effect on the life and properties of the elastomers Heat development in a rubber occurs when it is subjected to a variety of compressive stresses in service Heat evolution tests are commonly performed to estimate the quality of use and expected service life of various compounds or material options for end product applications New developments in recent years on test methods in this direction constitute an important part of the book At the same time corresponding simulation and modelling methods have been developed that contribute to a better understanding and enable the predictive simulation of self heating and the kinetics of temperature fields in complex cyclically loaded rubber components Specifically finite strain thermal viscoelastic damage models for predicting the cyclic thermomechanical response of rubber specimens under fatigue are also presented and analytical models for heat diffusion in stressed rubbers

Stability of Materials A. Gonis, Josef Kudrnovský, Patrice E.A. Turchi, 2012-12-06 Engineering materials with desirable physical and technological properties

requires understanding and predictive capability of materials behavior under varying external conditions such as temperature and pressure This immediately brings one face to face with the fundamental difficulty of establishing a connection between materials behavior at a microscopic level where understanding is to be sought and macroscopic behavior which needs to be predicted Bridging the corresponding gap in length scales that separates the ends of this spectrum has been a goal intensely pursued by theoretical physicists experimentalists and metallurgists alike Traditionally the search for methods to bridge the length scale gap and to gain the needed predictive capability of materials properties has been conducted largely on a trial and error basis guided by the skill of the metallurgist large volumes of experimental data and often ad hoc semi phenomenological models This situation has persisted almost to this day and it is only recently that significant changes have begun to take place These changes have been brought about by a number of developments some of long standing others of more recent vintage
