Taste & Smell

Taste & smell

Most of our special senses are chemoreception systems: gustation (taste) and olfaction (smell). The degree to which we respond to taste or olfaction, how many and what kind of receptors we possess, and how we respond to molecules dissolved in fluid (taste) and in the air (smell) are all determined by the number of receptors we have. The sense of taste is less discriminatory than the sense of smell, and there is an overlap between taste receptors. The sense of smell is highly discriminatory, with several types of olfactory receptors, each responding to particular molecules. Taste and olfaction are related to smell, vision, and hearing, in that they are all part of the human sensory system, but taste is particularly affected by the sense of smell.

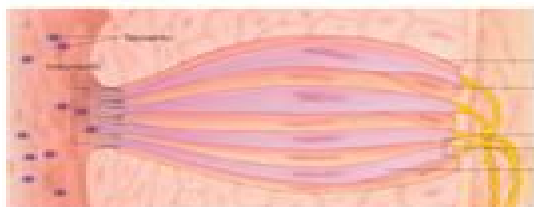

Concentrations

Taste receptors vary depending on the concentration of molecules in a given solution or solid. For low concentrations, taste is not as strong as for higher concentrations.

Gustation

Gustation, the sense of taste, gives us information about the food and drink that we consume. Taste buds on the primary gustatory organ, the tongue, contain chemoreceptors called gustatory cells. These taste buds have four basic components: sweet, sour, bitter and salty. A fifth taste, umami, or savory, has been reported. This flavor is associated with proteins, or its agent, glutamate or meat broth.

The taste bud

However, substances that produce taste, food with receptor molecules on the surface of the microvilli. The resulting receptor potential travels to the basal end of the gustatory cell, where the signal is electrically transmitted to the supporting cell for molecular transport. Gustatory cells live about 10 days, after which they are replaced by new cells generated from basal cells at the base of the taste buds.

Olfaction

The sense of smell is called olfaction, or the detection of odors. Olfaction depends on specialized chemical receptors, or chemoreceptors, located within the olfactory epithelium. These receptors are designed to respond to small amounts of an odorant, a molecule that can be smelled. The brain integrates the input from several different receptors to identify a particular odor. Humans can detect about 10,000 odors.

As air flows through the nose, the odors across the nasal cavity pass through the olfactory epithelium, bringing odorant molecules into contact with the olfactory neurons. Binding increases the ability to detect odors by increasing the volume of air inhaled, which can increase the number of receptors.

Olfactory receptors

Olfactory receptors

Olfaction depends on the olfactory epithelium, which is located in the olfactory bulb. The olfactory epithelium is a specialized tissue that is located in the olfactory bulb, which is the part of the brain that is responsible for the sense of smell. The olfactory epithelium is composed of olfactory neurons, which are specialized cells that are responsible for the sense of smell. The olfactory neurons are located in the olfactory bulb, which is the part of the brain that is responsible for the sense of smell.

Compound sweet and salty tastes, we are left with more receptors to detect umami, and about 1,000 receptors to detect bitter. The sense of taste is less discriminatory than the sense of smell, and there is an overlap between taste receptors. The sense of smell is highly discriminatory, with several types of olfactory receptors, each responding to particular molecules. Taste and olfaction are related to smell, vision, and hearing, in that they are all part of the human sensory system, but taste is particularly affected by the sense of smell.

The synapse

Neurons communicate with other cells at a synapse, the site of a nerve impulse transmission. The space between the presynaptic, or sending, neuron and the postsynaptic, or receiving, cell is called the synaptic cleft. An impulse enters at the top of the postsynaptic cell, the axon hillock, where "trigger" molecules called neurotransmitters. These highly specialized chemicals carry nerve impulses from the presynaptic cell to the postsynaptic cell, where they bind to receptors on the postsynaptic cell, which then triggers an action potential in the postsynaptic cell.
