

The background of the cover is a deep blue space filled with numerous galaxies and bright light sources. Some galaxies are clearly visible as spiral or elliptical structures, while others are just bright points of light. There are also faint, curved lines of light that suggest gravitational lensing or the paths of light rays being bent by massive objects. The overall effect is a sense of vastness and cosmic mystery.

Singularity Theory and Gravitational Lensing Arlie O. Petters, Harold Levine, Joachim Wambsganss, 2012-12-06
Astronomers do not do experiments They observe the universe primarily through detecting light emitted by stars and other luminous objects Since this light must travel through space to reach us variations in the metric of space affects the appearance of astronomical objects These variations lead to dramatic changes in the shape and brightness of astronomical sources Because these variations are sensitive to mass rather than to light observations of gravitational lensing enable astronomers to probe the mass distribution of the universe With gravitational lensing observations astronomers are addressing many of the most important scientific questions in astronomy and physics What is the universe made of Most of the energy and mass in the universe is not in the form of luminous objects Stars account for less than 1 % of the energy density of the universe Perhaps as much as another 3% of the energy density of the universe is in the form of warm gas that fills the space between galaxies The remaining 96% of the energy density is in some yet unidentified form Roughly one third of this energy density of the universe is dark matter matter that clusters gravitationally but does not emit light Most cosmologists suspect that this dark matter is composed of weakly interacting subatomic particles However most of the energy density of the universe appears to be in an even stranger form energy associated with empty space *The Relativistic Boltzmann Equation: Theory and Applications* Carlo Cercignani, Gilberto M. Kremer, 2012-12-06 The aim of this book is to present the theory and applications of the relativistic Boltzmann equation in a self contained manner even for those readers who have no familiarity with special and general relativity Though an attempt is made to present the basic concepts in a complete fashion the style of presentation is chosen to be appealing to readers who want to understand how kinetic theory is used for explicit calculations The book will be helpful not only as a textbook for an advanced course on relativistic kinetic theory but also as a reference for physicists astrophysicists and applied mathematicians who are interested in the theory and applications of the relativistic Boltzmann equation Gravitational Lensing and Optical Geometry Marcus C. Werner, 2020-12-08 The year 2019 saw the centenary of Eddington's eclipse expeditions and the corroboration of Einstein's general relativity by gravitational lensing To mark the occasion a Special Issue of Universe has been dedicated to the theoretical aspects of strong gravitational lensing The articles assembled in this volume contain original research and reviews and apply a variety of mathematical techniques that have been developed to study this effect both in 3 space and in spacetime These include Mathematical properties of the standard thin lens approximation in particular caustics Optical geometry the Gauss Bonnet method and related approaches Lensing in the spacetime of general relativity and modified theories black hole shadows **Principles of Gravitational Lensing** Arthur B. Congdon, Charles R. Keeton, 2018-12-01 This textbook provides an introduction to gravitational lensing which has become an invaluable tool in modern astrophysics with applications that range from finding planets orbiting distant stars to understanding how dark

matter and dark energy conspired to form the cosmic structures we see today *Principles of Gravitational Lensing* begins with Einstein's prediction that gravity bends light and shows how that fundamental idea has spawned a rich field of study over the past century The gravitational deflection of light was first detected by Eddington during a solar eclipse in May 1919 launching Einstein and his theory of relativity into public view Yet the possibility of using the phenomenon to unlock mysteries of the Universe seemed remote given the technology of the day Theoretical work was carried out sporadically over the next six decades but only with the discovery of the system Q0957 561 in 1979 was gravitational lensing transformed from a curiosity of general relativity into a practical observational tool This book describes how the three subfields known as strong lensing weak lensing and microlensing have grown independently but become increasingly intertwined Drawing on their research experience Congdon and Keeton begin with the basic physics of light bending then present the mathematical foundations of gravitational lensing building up to current research topics in a clear and systematic way Relevant background material from physics and mathematics is included making the book self contained The derivations and explanations are supplemented by exercises designed to help students master the theoretical concepts as well as the methods that drive current research An extensive bibliography guides those wishing to delve more deeply into particular areas of interest *Principles of Gravitational Lensing* is ideal for advanced students and seasoned researchers looking to penetrate this thriving subject and even contribute research of their own

Real and Complex Singularities Laurentiu Paunescu, 2007 The modern theory of singularities provides a unifying theme that runs through fields of mathematics as diverse as homological algebra and Hamiltonian systems It is also an important point of reference in the development of a large part of contemporary algebra geometry and analysis Presented by internationally recognized experts the collection of articles in this volume yields a significant cross section of these developments The wide range of surveys includes an authoritative treatment of the deformation theory of isolated complex singularities by prize winning researcher K Miyajima Graduate students and even ambitious undergraduates in mathematics will find many research ideas in this volume and non experts in mathematics can have an overview of some classic and fundamental results in singularity theory The explanations are detailed enough to capture the interest of the curious reader and complete enough to provide the necessary background material needed to go further into the subject and explore the research literature

Gravitational Lensing: Strong, Weak and Micro Peter Schneider, Christopher Kochanek, Joachim Wambsganss, 2006-12-30 The observation in 1919 by A S Eddington and collaborators of the gravitational deflection of light by the Sun proved one of the many predictions of Einstein's Theory of General Relativity The Sun was the first example of a gravitational lens In 1936 Albert Einstein published an article in which he suggested using stars as gravitational lenses A year later Fritz Zwicky pointed out that galaxies would act as lenses much more likely than stars and also gave a list of possible applications as a means to determine the dark matter content of galaxies and clusters of galaxies It was only in 1979 that the first example of an extragalactic gravitational lens was provided

by the observation of the distant quasar QSO 0957 0561 by D Walsh R F Carswell and R J Weymann A few years later the first lens showing images in the form of arcs was detected The theory observations and applications of gravitational lensing constitute one of the most rapidly growing branches of astrophysics The gravitational deflection of light generated by mass concentrations along a light path produces magnification multiplicity and distortion of images and delays upon propagation from one line of sight relative to another The huge amount of scientific work produced over the last decade on gravitational lensing has clearly revealed its already substantial and wide impact and its potential for future astrophysical applications

A Geometric Approach to Thermomechanics of Dissipating Continua Lalao Rakotomanana,2012-09-08 Across the centuries the development and growth of mathematical concepts have been strongly stimulated by the needs of mechanics Vector algebra was developed to describe the equilibrium of force systems and originated from Stevin's experiments 1548 1620 Vector analysis was then introduced to study velocity fields and force fields Classical dynamics required the differential calculus developed by Newton 1687 Nevertheless the concept of particle acceleration was the starting point for introducing a structured spacetime Instantaneous velocity involved the set of particle positions in space Vector algebra theory was not sufficient to compare the different velocities of a particle in the course of time There was a need to parallel transport these velocities at a single point before any vector algebraic operation The appropriate mathematical structure for this transport was the connection I The Euclidean connection derived from the metric tensor of the referential body was the only connection used in mechanics for over two centuries Then major steps in the evolution of spacetime concepts were made by Einstein in 1905 special relativity and 1915 general relativity by using Riemannian connection Slightly later nonrelativistic spacetime which includes the main features of general relativity I It took about one and a half centuries for connection theory to be accepted as an independent theory in mathematics Major steps for the connection concept are attributed to a series of findings Riemann 1854 Christoffel 1869 Ricci 1888 Levi Civita 1917 Weyl 1918 Cartan 1923 Eshermann 1950

Homogenization of Partial Differential Equations Vladimir A. Marchenko,Evgueni Ya. Khruslov,2008-12-22 Homogenization is a method for modeling processes in microinhomogeneous media which are encountered in radiophysics filtration theory rheology elasticity theory and other

domains of mechanics physics and technology These processes are described by PDEs with rapidly oscillating coefficients or boundary value problems in domains with complex microstructure From the technical point of view given the complexity of these processes the best techniques to solve a wide variety of problems involve constructing appropriate macroscopic homogenized models The present monograph is a comprehensive study of homogenized problems based on the asymptotic analysis of boundary value problems as the characteristic scales of the microstructure decrease to zero The work focuses on the construction of nonstandard models non local models multicomponent models and models with memory Along with complete proofs of all main results numerous examples of typical structures of microinhomogeneous media with their corresponding homogenized models are provided Graduate students applied mathematicians physicists and engineers will benefit from this monograph which may be used in the classroom or as a comprehensive reference text **Topics in**
