Physicochemical theoretical development has been dwarfed by the abundant experimental achievements in molecular recognition studies, including the template effects reported in this book [1–3]. The traditional thermodynamics of the steam engine deals with molecules without any molecular discrimination: their kinetic energy is of the sole concern. Whether the steam is made of normal water, H₂O, or expensive deuterated water, D₂O, or the working gas is composed of some other molecules, it does not matter. The piston in the engine recognizes the gas molecules in the same way that a peasant in a remote Chinese village might recognize the laborers he would like to employ. He might concern himself only with whether the laborers are strong enough to drag a plough in his fields. He might even not want to distinguish if the power is provided by a man or a horse. However, now suppose a professor (e.g., one of the editors, Diederich [2a], from ETH Zurich) wants to accept somebody to work with him in his group. He would not take a horse, or even a lay person. Even most chemists might not be good enough candidates. Diederich's recognition is much more specific.

In the examples provided in this book the piston or the peasant are replaced by a professor-like template. Here, the thermodynamics that describes a "peasant and animal power" relationship becomes inadequate to explain many phenomena concerning the attractive interactions of molecules: sometimes these are the same, such as the case of hydrophobic molecules; sometime they are of contrasting properties, such as donor or ligand and acceptor, or substrate and enzyme. For example, both the similarity rule and the complementarity rule are still empirical rules. A natural guess would be that information-
