Throughput Analysis of Manual Order Picking Systems with Congestion Consideration Christian Huber,2014-09-03

Throughput in manual order picking systems with narrow aisles suffers from congestion as pickers cannot pass each other Only few models incorporate congestion but they have very strict assumptions In this work queueing theory is used to analyze systems with traversal routing as well as different storage policies The models are able to estimate throughput for many alternative designs in a relatively short amount of time New guidelines for narrow aisle order picking systems are introduced

Interference Mitigation with Selective Retransmissions in Wireless Sensor Networks Selig, Marc,2016 A wireless sensor network with single antenna sensors on the transmitter side and an access point AP equipped with multiple antennas on the receiver side is considered In order to reduce the number of outages resulting from the noise amplification by the linear reconstruction within the successive interference cancellation SIC procedure the AP is given the possibility to request retransmissions of signals from selected sensors in a subsequent time slot TS In case retransmissions are needed also in the subsequent time slot the AP postpones the signal detection until all requested signals have been retransmitted making the signal detection a recursive procedure The number of sensors required to retransmit depends on the order of the processed sensor signals within the SIC procedure We propose an optimal algorithm based on a QR decomposition and a depth first search through all possible decoding orders which finds the decoding order necessitating a minimum number of retransmissions suitable for zero forcing ZF and minimum mean square error MMSE linear reconstruction approaches Since the computational complexity of the optimal algorithm is high different suboptimal algorithms with lower computational complexity are proposed for the case of ZFSIC and MMSE SIC respectively The recursive nature of the retransmission procedure may lead to an unlimited detection delay because the linear reconstruction followed by SIC starts only when no sensor needs a retransmission from the previous TS By reducing the number of transmitting sensors for a fixed number of receiving antennas the receive diversity of the AP can be exploited which leads to less retransmissions Therefore we propose an optimal transmit policy which selects the best set of sensors to maximize the system throughput This optimal transmit policy is found by means of a Markov decision process in combination with dynamic programming
